

Suppressing the killer instinct

Kerry S. Campbell*

Natural killer (NK) cells are innate lymphoid cells that have adopted activating and inhibitory signaling mechanisms enabling them to be tolerant of normal cells but to distinguish and eliminate tumor cells and virus-infected cells. In this issue of *Science Signaling*, Matalon *et al.* show how inhibitory receptors disrupt NK cell activation by stimulating dephosphorylation of the adaptor protein LAT (linker of activated T cells) and phospholipase C- γ by the phosphatase SHP-1 [Src homology 2 (SH2) domain-containing protein tyrosine phosphatase 1], as well as ubiquitylation of LAT by Cbl family E3 ubiquitin ligases.

Natural killer (NK) cells are a subset of innate lymphoid cells that constitutes an ideal cellular model system with which to study signal transduction cross-talk (1). These cells are regulated by a dynamic balance of positive and negative signals transduced from a wide range of germline-encoded activating, inhibitory, and adhesion receptors. As NK cells probe the surfaces of adjacent cells in the body, many activating receptors can be triggered by their ligands, but an array of inhibitory receptors simultaneously engages with major histocompatibility class I (MHC-I) molecules on the healthy cells to dominantly disrupt adhesion and suppress activation signaling. Whereas most healthy cells express MHC-I, tumor cells or virus-infected cells commonly reduce the cell surface abundance of MHC-I and thereby avoid detection by cytolytic T cells. In so doing, however, these abnormal MHC-I-deficient cells become prime targets for NK cell-mediated attack, because they lack inhibitory receptor ligands. Activation signaling predominates when NK cells encounter an MHC-I-deficient target cell or a target cell with an overwhelming abundance of activating receptor ligands. Activation signaling initiates strong adhesion, cytoskeletal polarization, and the targeted mobilization of lytic granules to release perforins and granzymes toward the NK immunological synapse (NKIS), which efficiently and selectively initiates apoptosis of the abnormal cell (2).

Killer cell immunoglobulin-like receptors (KIRs) are a family of highly polymorphic in-

hibitory and activating receptors that bind to MHC-I and are expressed on most NK cells and some T cells in humans (1). Different inhibitory KIR family members recognize distinct subsets of the diverse allotypes of MHC-I in humans [human leukocyte antigen A (HLA-A), HLA-B, and HLA-C], and distinct KIR family members are differentially expressed on a person's individual NK cells to create a diverse cell repertoire with disparate KIR expression profiles and MHC-I detection capacities. Expression of a KIR that recognizes an endogenous MHC-I molecule not only tolerizes a mature NK cell to prevent indiscriminate cytolysis of normal cells, but also "educates" or "licenses" a developing NK cell to become functionally mature. Therefore, inhibitory KIRs are key regulators of human NK cell function, and both functional properties depend on downstream inhibitory signaling pathways.

Like those on T and B cells, most activating receptors on NK cells transduce signals on the basis of protein tyrosine kinase (PTK)-mediated signaling, much of which is initiated through immunoreceptor tyrosine-based activation motifs (ITAMs) (3). The predominant PTKs that initiate activation signaling are believed to be Src family kinases (SFKs), particularly Lck and Fyn, which phosphorylate ITAMs on activating receptor-associated transmembrane adaptor proteins—such as DAP12 (DNAX-activation protein of 12 kDa), T cell receptor ζ , or Fc receptor γ —which can then recruit and activate ZAP70 (ζ chain-associated protein kinase of 70 kDa) or Syk family PTKs. Activation of these PTKs initiates a cascade of tyrosine phosphorylation-centric downstream signaling events to drive degranulation and the subsequent production of an array of cyto-

kines and chemokines, notably interferon- γ and tumor necrosis factor- α , to promote inflammatory responses.

The central element of inhibitory signaling by KIRs is their recruitment of the protein tyrosine phosphatases SHP-1 [Src homology 2 (SH2) domain-containing protein tyrosine phosphatase 1] and SHP-2 to two phosphorylated cytoplasmic immunoreceptor tyrosine-based inhibitory motifs (ITIMs; V/IxYxxL) upon engagement with MHC-I on target cells (3). Whereas SHP-1 recruitment appears to require SFK-mediated phosphorylation of both tyrosine residues in the ITIM, evidence indicates that SHP-2 can bind weakly to KIR even in the unphosphorylated state but more avidly upon phosphorylation of the N-terminal ITIM (4). Although Lck and SHP-1 are rapidly recruited to the center of the inhibitory NKIS (iNKIS) (5), tyrosine phosphorylation of KIRs appears to be particularly transient and occurs with Lck in microclusters at the iNKIS, as opposed to uniformly across the entire interface (6). Furthermore, Abeyweera *et al.* showed that the initiation of inhibitory KIR signaling induces rapid disruption of activating receptor microclusters, remodeling of the actin cytoskeleton, and retraction of the NK cell from the target cell (7).

A key question persists: What are the critical substrates that are dephosphorylated by SHP-1 and SHP-2 to efficiently terminate activation signaling? Early studies to answer this question used substrate-trapping mutants of SHP-1 to capture putative substrates. Stebbins *et al.* used a KIR-trapping SHP-1 chimeric receptor as an *in vivo* approach to identify the SHP-1 substrate, Vav-1, upon KIR engagement with MHC-I on target cells (8). Vav-1 is considered to be a critical target for early termination of the NK cell activation pathway by inhibitory KIRs, because it is an essential guanine nucleotide exchange factor that activates the Rho family guanosine triphosphatase Rac-1 to initiate polymerization of the actin cytoskeleton, promote adhesion with the target cell, and instigate the recruitment of lytic granules to the iNKIS. However, the dephosphorylation of a single effector protein by SHP-1 has seemed too simplistic, and a larger repertoire of substrates has long been suspected and anticipated.

The article by Matalon *et al.* in this issue of *Science Signaling* (9) makes a substantial advance in expanding our understanding of the molecular mechanism of inhibitory KIR signaling (Fig. 1). The authors present a set

Fig. 1. Proposed model for the negative effects of inhibitory KIRs on LAT-PLC- γ signaling. Activating receptors engaged by ligands on a target cell stimulate the phosphorylation of Tyr¹³² (pY132) of LAT to recruit and activate PLC- γ through tyrosine phosphorylation (pY), which results in Ca²⁺ signaling. Co-engagement of KIR with MHC-I on the target cell stimulates the SFK-mediated phosphorylation of cytoplasmic ITIMs, which results in the recruitment and activation of SHP-1. Activated SHP-1 dephosphorylates PLC- γ and Tyr¹³² of LAT to disrupt its association with PLC- γ and abrogate enzymatic function. In addition, Cbl-b and c-Cbl are activated by the engagement of inhibitory KIRs with MHC-I to polyubiquitylate (Ub) LAT at Lys⁵² (K52), Lys²⁰⁴ (K204), or both, which stimulates the subsequent proteasomal degradation of the adaptor protein to further diminish activation signaling capacity. [Figure adapted from Matalon *et al.* (9)]

of experiments using standard protein biochemistry, small interfering RNA (siRNA)-mediated silencing and reconstitution methods, and fluorescence resonance energy transfer technology in NK cell lines and primary NK cells. This work provides evidence that SHP-1 directly associates with and dephosphorylates LAT (linker of activated T cells), phospholipase C- γ 1 (PLC- γ 1), and PLC- γ 2 to disrupt their aggregation when the inhibitory receptor is engaged with a ligand (HLA-Cw4) on target cells. LAT is a transmembrane adaptor protein that nucleates PLC- γ 1, PLC- γ 2, the adaptor protein SLP-76 (SH2 domain-containing leukocyte protein of 76 kDa), and the adaptor Grb2 through phosphotyrosine-mediated interactions, and activation of PLC- γ initiates downstream Ca²⁺ signaling, which is required for degranulation responses by cytolytic lymphocytes. These findings substantially expand upon earlier observations (10) to support a mechanism by which inhibitory KIRs terminate early tyrosine phosphorylation-dependent activation signaling events to disrupt the assembly of an essential protein complex.

In addition, the work of Matalon *et al.* further uncovered another critical piece of the puzzle by which engagement of inhibitory KIRs disrupts the assembly of the LAT-PLC- γ signaling complex through ubiquitylation of LAT by the Cbl family E3 ubiquitin ligases. Previous work by Peterson and Long established that activation signaling in human NK cells results in the physical association between the tyrosine-phosphorylated Vav-1 and c-Cbl and that this association is disrupted in a SHP-1-dependent manner when inhibitory KIRs are engaged by a ligand (11). Demonstrating the strong suppressive effect of Cbl family members, disruption of Cbl-b activity in NK cells markedly potentiates their anti-tumor response (12). Matalon *et al.* have extended these observations by showing that LAT is ubiquitylated on lysine residues when KIRs are engaged with MHC-I and that siRNA-mediated knockdown of both Cbl-b and the related c-Cbl abrogated LAT ubiquitylation. Furthermore, the authors showed that simultaneous siRNA-mediated silencing of both E3 ligases effectively abolished the capacity of KIR to inhibit both Ca²⁺ signaling

and cytotoxicity toward MHC-I ligand-bearing target cells.

In summary (Fig. 1), this study by Matalon *et al.* has revealed two key elements of the mechanism by which inhibitory KIRs suppress activating signaling pathways in human NK cells: (i) the tyrosine-dephosphorylation of LAT and PLC- γ by SHP-1 to disrupt their association and the activation of PLC- γ , and (ii) the ubiquitylation of LAT by Cbl family E3 ligases. Although additional work is necessary to further dissect the interplay between these newly defined pathways and the means by which Cbl-b and c-Cbl are activated, our understanding of the molecular mechanisms suppressing the killer instinct of NK cells has come of age.
